1. Introduction

Definition of keyloggers.

A keylogger is a form of surveillance technology that can monitor and record each keystroke made on a particular computer. It is sometimes referred to as a keystroke logger or keyboard capture, depending on the context. It is also possible to install keylogger software on mobile devices like the Apple iPhone and Android-based gadgets, among others. In order for hackers to obtain personally identifiable information (PII), login passwords, and sensitive organisational data, keyloggers are frequently employed as a spyware weapon. There are a few applications for keyloggers that may, to differing degrees, be seen as ethical or appropriate. Keylogger recorders can also be used by employers to monitor the computer activities of their employees, parents to monitor the internet usage of their children, device owners to monitor any potentially unauthorised activity on their devices, law enforcement agencies to investigate incidents involving computer use, and so on. (Gillis, *What is a keylogger? definition from searchsecurity* 2021)

A keylogger's primary purpose is to monitor and record your keystrokes before sending those logs in some form or another to the person who installed the keylogger on your computer. The fact that most of your interactions with your computer and with the people you communicate with via your computer are mediated through your keyboard means that the range of potential information that a snooper can acquire by using this method is truly vast. This range of information includes everything from passwords and banking information to private correspondence.

Some keyloggers not only record the text that is typed but also spy in a variety of different ways in addition to capturing the keystrokes that are typed. It is possible for more sophisticated keyloggers to Log clipboard text, which records information that you cut and paste from other documents; Track activity, such as opening folders, documents, and applications; Take and record randomly timed screenshots; and even Request the text value of certain on-screen controls, which can be helpful for grabbing passwords. (Fruhlinger, *Keyloggers explained: How attackers record computer inputs* 2022)

Types of Keyloggers

Keyloggers can be either hardware- or software-based, depending on how they collect data. Keylogger tools are all essentially built for the same thing. However, they are fundamentally different in terms of both their methodologies and physical design.

A hardware-based keylogger is a small hardware device that plugs into the keyboard and steals data. It is easy for someone who wants to monitor your activity to hide this device

because it appears like a regular PS/2 keyboard connection, computer cable, or USB adapter.

Keylogger software may be installed on a computer even if the attacker does not have physical access to the machine. A person who wishes to keep tabs on a computer can download it on deliberately, or it might be installed secretly as part of a rootkit or a remote administration Trojan (RAT). (Popovici, *What is a keylogger? definition, types, examples and prevention* 2022)

Hardware Based Keyloggers

A Hardware-Based keylogger has to be physically inserted into a computer or installed nearby the targeted machine. Due to this, direct access is required, which is a difficult task that is often accomplished using social engineering tactics or a compromised insider.

A keylogger that is based on hardware can include recording devices that can be inserted in the wiring of the keyboard itself. Alternatively, a keylogger might be designed to look like a USB thumb drive and slid into a port on a laptop or a computer. There are additional devices on the market that are capable of recording the Bluetooth conversation that takes place between a wireless keyboard and a computer.

An acoustic keylogger is a particularly exotic type of keylogger that has been tested in the lab. This type of keylogger is able to discern with amazing precision what you are typing only solely on the sounds that your fingers create while they are on the keys. The concept of third-party recording, which simply consists of a camera being covertly aimed at your screen and keyboard, which is one of the simpler form of Hardware based Keyloggers. (Fruhlinger, *Keyloggers explained: How attackers record computer inputs* 2022)

It's possible for a hardware keylogger to appear in the shape of a module that's meant to be put right inside the keyboard itself. When the user writes on the keyboard, the keylogger records each keystroke and stores it as text on its own hard drive. The memory capacity of the keylogger's hard drive might be as high as several gigabytes. There is another type of wireless keylogger known as a wireless keylogger sniffer. This type of wireless keylogger sniffer is able to capture and decode data packets that are sent between a wireless keyboard and its receiver. (Gillis, *What is a keylogger? definition from searchsecurity* 2021)

Software Based Keyloggers

These are programmes that are installed on your device and record everything you do, including the keystrokes you type.

A user mode keylogger, often known as an API-level keylogger, is perhaps the most popular variety of keylogger software. Although these programmes do not have administrator capabilities, they are nonetheless able to intercept information that is being broadcast via the application programming interfaces (APIs) that are responsible for allowing various apps to accept input from the keyboard. These keyloggers monitor GetAsyncKeyState or GetKeyState API methods on Microsoft Windows and utilise a DLL to capture the data that they gather.

Once they are installed, kernel-level keyloggers get their hooks into the operating system itself, making it more difficult to detect and remove them. However, creating and installing these keyloggers is more complex than other types of keyloggers. On the other end of the spectrum are screen scrapers and browser-level keyloggers. Screen scrapers do not log keystrokes but rather use the computer's screenshot capabilities to record onscreen text. Browser-level keyloggers can only detect text entered into a browser form; however, given how much of our online life takes place within a web browser, this is still a pretty dangerous. (Fruhlinger, *Keyloggers explained: How attackers record computer inputs* 2022)

The files that make up a standard software keylogger are a dynamic link library (DLL) file that actually accomplishes the recording and an executable file that both installs the DLL file and prompts it to start recording. These files are typically installed in the same directory together. The keylogger software keeps a track of every keystroke that is typed by the user and sends the information to the person who originally installed the programme through the internet at regular intervals. Hackers are able to develop software that logs keystrokes by employing keyboard application programme interfaces (APIs) from one application to another, malicious script injection, or memory injection. (Gillis, *What is a keylogger? definition from searchsecurity* 2021)

History of Keyloggers

The usage of keyloggers may be traced back to the 1970s, when the Soviet Union created a hardware keylogging device for electric typewriters. This marked the beginning of the widespread use of keyloggers. By analysing the changes in magnetic field strength caused by the motion of the printer, the keylogger, also known as the Selectric bug, was able to monitor and record the location of the printhead. The IBM Selectric typewriters were the subject of the Selectric bug, which spied on United States diplomats working in the United States embassy and consulate facilities in Moscow and St. Petersburg. Keyloggers made by Selectric were discovered in 16 different typewriters. These keyloggers had been in use until 1984, when they were discovered by a U.S. ally who was a distinct target of this operation.

A software keylogger that was built by Perry Kivolowitz in 1983 is an example of another early keylogger. The character list dumps were found and dumped by the user mode keylogger that was in a Unix kernel.

The usage of keyloggers has been increasingly widespread, particularly during the 1990s. The development of additional keylogger software meant that attackers no longer needed to install hardware keyloggers. This made it possible for attackers to obtain confidential data, such as credit card information, from victims who were unaware of the attack and were located in a remote location. The usage of keyloggers began to target home users for the goal of fraud, in addition to users in a variety of businesses for the purpose of phishing.

After an incident in which a keylogger was discovered at hotels in Dallas, Texas, the United States Department of Homeland Security started issuing warnings to hotel owners regarding keyloggers in 2014. This was in 2014. Computers that are open to the public or that are located in communal spaces are prime locations for keyloggers.

A keylogger was smuggled inside a modification for the video game Grand Theft Auto V in the year 2015. It was also discovered in 2017 that HP laptops included a keylogger, which the company patched out after stating that the keyloggers were employed as a tool for troubleshooting the software. (Gillis, *What is a keylogger? definition from searchsecurity* 2021)

Keylogger Detection

Since there are numerous types of keyloggers, each of which employ a unique mechanism, there is no one detection or eradication method that is universally acknowledged as being the most efficient. Due to the fact that keyloggers are able to make changes to the kernel of an operating system, checking the Task Manager of a computer is not always sufficient to identify a keylogger.

By comparing the files on a computer with a keylogger signature base or a checklist of common keylogger attributes, security software, such as an anti-keylogger software programme, is designed specifically to scan for software-based keyloggers. This is accomplished by scanning for software-based keyloggers. It's possible that using a programme that stops keyloggers will be more successful than using an antivirus or antispyware tool. It is possible for the latter to mistakenly recognise a keylogger as a normal software rather than malware.

It is possible that an antispyware application, depending on the method that it employs, will be able to discover and deactivate keylogger malware that possesses lesser privileges than it does. The usage of a network monitor will guarantee that the user is

warned each time an application tries to create a network connection, allowing a security team the opportunity to block any potential keylogger activity that may be taking place. (Gillis, *What is a keylogger? definition from searchsecurity* 2021)

if a keylogger is hardware-based, you should look for the hardware itself. If there's a strange-looking flash drive or other device hooked into your computer, you should remove it immediately. From time to time, it's a good idea to peek behind your workplace desktop and see if anything unusual has been added. (Fruhlinger, *Keyloggers explained: How attackers record computer inputs* 2022)

2. Experiment Setup

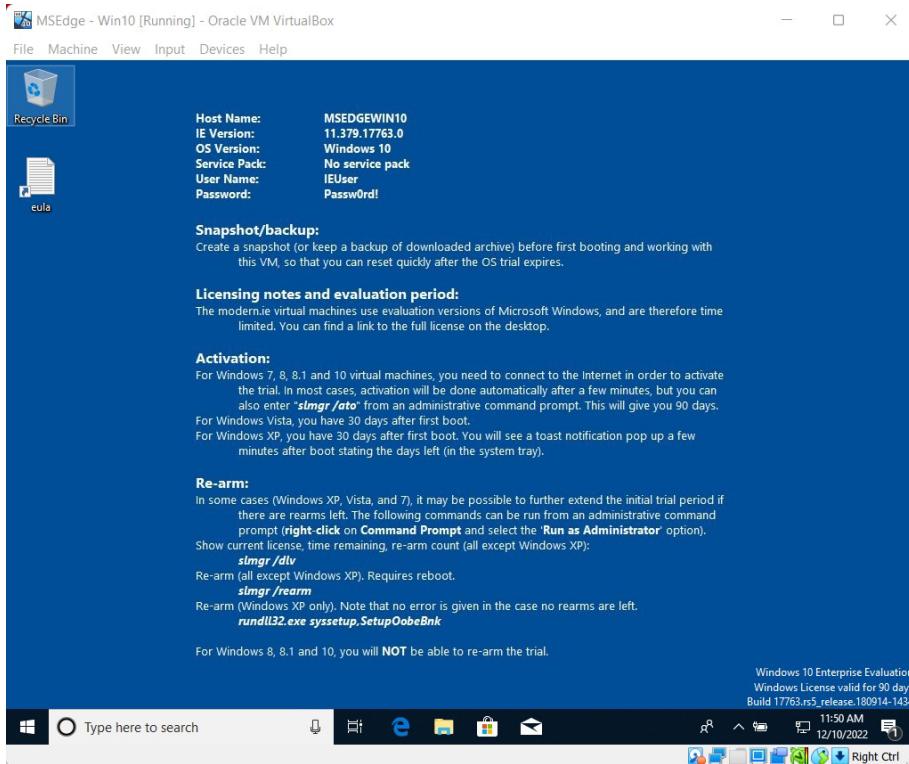

The VirtualBox was used as the virtualization software and as for the operating system, MSEdge on Win 10 (x64) was utilized. The operating system consumed 4096MB of Ram and 38.5GB of storage space after installing all the required tools for malware analysis and creating snapshot as well in Virtual Box so that we are able to revert back if things go wrong or anything becomes corrupt when we are analyzing the malware. The Windows defender and security protection had to be disabled prior to our analysis. There were numerous tools used in this analysis, majority of them were taken from the labs we did. Additionally 4 other tools were utilized as well which were not part of this units lab tutorials which was required for the completion of Advanced Task 1. The Keylogger Executable required GIT and Python inorder to be executed. GIT was used to Clone the Keylogger Executable from the Glithub page and Python which required inorder to execute the Keylogger Executable. We had to create an Outlook Email as well inorder to receive the Keylogger's result.

Setting Up of the New VM

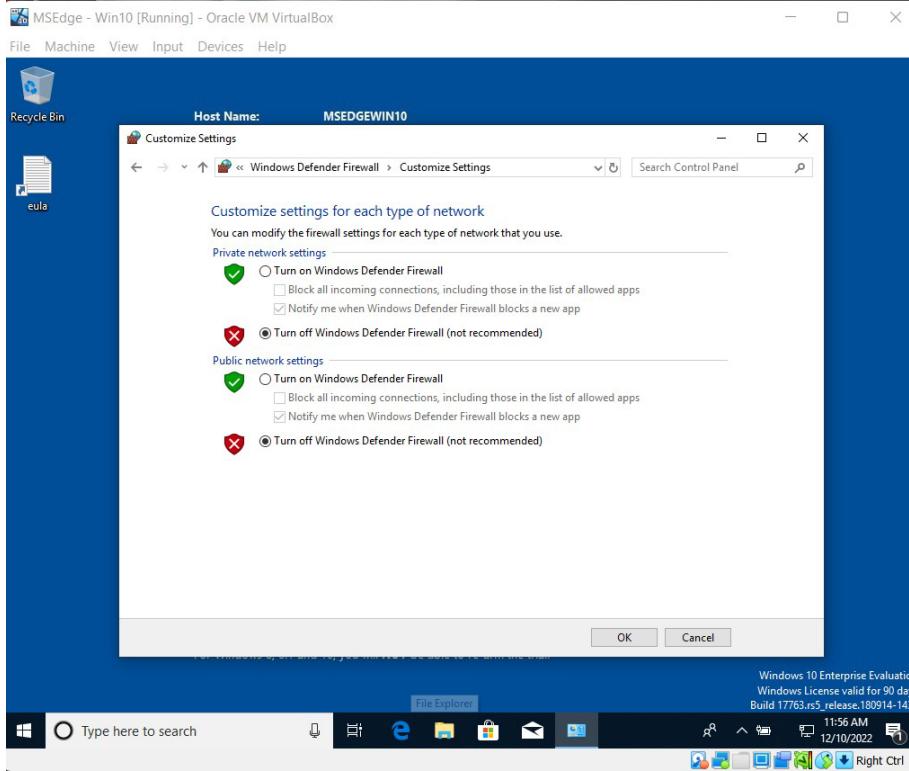

1. The Virtual Machine was sourced from <https://developer.microsoft.com/en-us/microsoft-edge/tools/vms/>. MSEdge on Win10 (x64) Stable 1809 was installed for VirtualBox.

The screenshot shows the Microsoft Edge Developer VMs download interface. At the top, there is a navigation bar with the Microsoft logo, 'Microsoft Edge Developer', and links for 'Resources', 'Web Platform', 'Tools', 'Support', and 'Careers'. Below the navigation bar, the URL 'Home \ Tools \ VMs' is visible. The main heading is 'Virtual Machines'. A sub-headline says 'Test IE11 and Microsoft Edge Legacy using free Windows 10 virtual machines you download and manage locally'. Below this, there is a section titled 'Select a download' with a dropdown menu set to 'MSEdge on Win10 (x64) Stable 1809'. Another dropdown menu for 'Choose a VM platform:' is set to 'VirtualBox'. At the bottom, there is a blue button labeled 'Download .zip >'. The entire interface is clean and modern, typical of Microsoft's developer tools.

2. Snippet after successful installation of the Virtual Machine.

3. Disabling Windows Defender and Virus and Threat Protection Settings.

The screenshot shows the Windows Security interface with the title "Windows Security". Under the heading "Virus & threat protection settings", it says "View and update Virus & threat protection settings for Windows Defender Antivirus." There are two main sections: "Real-time protection" and "Cloud-delivered protection".

Real-time protection: Described as locating and stopping malware from installing or running on your device. It shows a warning that "Real-time protection is off, leaving your device vulnerable." A toggle switch is set to "Off".

Cloud-delivered protection: Described as providing increased and faster protection with access to the latest protection data in the cloud. It shows a warning that "Cloud-delivered protection is off. Your device may be vulnerable." A toggle switch is set to "Off".

Now the Virtual Machine was ready for Malware Analysis.

Description of Analysis Tools used

1. PEview

PE Viewer is a convenient and easy-to-use tool for viewing PE structures. It offers editing capabilities to change PE headers to correct corrupt PE files. To see imported DLLs and functions of any Windows 32- or 64-bit files, use the utility. Identify the exported functions and the offset at which they begin to run. Beginners who wish to learn about PE file structure may find this to be a useful tool. It is also a fantastic tool for analysing viruses and malware. (Viewer, Pe Viewer)

2. PEiD

PEiD is a lightweight programme used to identify popular compilers, packers, and cryptors. Virus authors frequently make an effort to pack or obfuscate their malware to make it more difficult to detect and analyse. When loaded from a text file named userdb, the current version of PEiD can identify over 470 distinct signatures in PE files. (Hacking Tutorials, 2017)

3. BinText

BinText is a text extractor and file scanner that aids in locating character strings hidden within binary files. The application can extract text from any type of file and display Resource strings, plain ASCII text, and Unicode (double byte ANSI) text. In the "Advanced" mode, each item has additional helpful information. The application will, in a novel way, display both the file offset and the memory offset of each string discovered. (Tpr, Bintext)

4. Dependency Walker

Any 32-bit or 64-bit Windows module (exe, dll, ocx, sys, etc.) may be scanned by the Dependency Walker, which creates a hierarchical tree diagram of all dependant modules. It shows all the functions that are exported by each module it finds, along with which of those functions other modules have actually called. Detailed information about each file, including its entire path, base address, version numbers, machine type, debug information, and more, is also shown in another view along with the minimal set of files that are necessary. (Dependency walker (depends.exe) Home Page)

5. Process Explorer

You may see information about the handles and DLLs that processes have opened or loaded in Process Explorer. There are two sub-windows in the Process Explorer display. The information displayed in the bottom window depends on the mode that Process Explorer is in; if it is in DLL mode, you will see the DLLs and memory-mapped files that the process has loaded. The top window always displays a list of the currently active processes, along with the names of their owning accounts. Powerful search features in Process Explorer allow you to easily identify processes that have specific handles opened or DLLs loaded. (Markruss, Process explorer - sysinternals)

6. Process Monitor

Process Monitor is a sophisticated Windows monitoring programme that displays process/thread activity, file system activity, and registry activity in real time. It combines the capabilities of two venerable Sysinternals tools, Filemon and Regmon, and adds a long list of upgrades, such as comprehensive event properties like session IDs and user names, trustworthy process information, full thread stacks with integrated symbol support for each operation, simultaneous logging to a file, and much more. (Markruss, Process Monitor - Sysinternals)

7. HashCalc

A quick and simple calculator that makes it possible to calculate message digests, checksums, and HMACs for files, text, and hex strings. It provides a selection of 13 of

the most widely used hash and checksum methods. (HashCalc - hash, CRC, and HMAC Calculator)

8. PEStudio

PEStudio's objective is to identify executable file artefacts in order to facilitate and quicken malware initial assessment. Globally, Digital-Forensic Labs, Security Operations Centers, and Computer Emergency Response Teams (CERT) use the technology. PEStudio is totally portable and works on any Windows platform; no installation is necessary. The system is not altered by PEStudio, and nothing is left behind. (PEStudio 2022)

9. Wireshark

Wireshark is an open-source packet analyzer that is free to use. It is employed in education, analysis, software development, and the design of communications protocols for networks. Cross-platform Wireshark uses pcap to capture packets and the Qt widget toolkit for its user interface in more recent releases, which also make it cross-platform. With the exception of its graphical user interface and integrated sorting and filtering functionality, Wireshark and tcpdump are comparable programmes. (Wireshark 2022)

Description of 4 Additional Analysis Tools used

1. Fiddler

The Fiddler tool records network traffic between the Internet and test PCs to assist with web application debugging. With the help of the tool, you can look at both incoming and outgoing data to keep track of and alter requests and answers before the browser sees them. A robust event-based scripting subsystem is also included in Fiddler, which you may expand using any .NET Framework language.

By creating an offline replica of the test site, Fiddler and the HTTP replay features can assist you in troubleshooting client-side problems with web applications. With the help of these tools, you may capture offline photos of the browsing session, package them, and do further analysis to get more in-depth diagnostic data. (QuinnRadich, Fiddler web debugger tool for internet explorer - win32 apps)

2. RegShot

Regshot is an open-source (LGPL) registry comparison tool that enables you to rapidly take a snapshot of your registry and then compare it with a second one—done after making system modifications or installing new software—in order to identify any registry changes. (Regshot)

3.ApateDNS

A simple-to-use GUI is provided by ApateDNS, an utility for managing DNS answers. By listening on UDP port 53 on the local system, ApateDNS acts as a false DNS server by forging DNS replies sent to a user-specified IP address. Additionally, ApateDNS instantly configures localhost as the DNS server. It restores the initial local DNS settings when the tool is closed. (ApateDNS)

4.AutoRuns

This tool, which has the most thorough understanding of auto-starting locations of any startup monitor, displays the programmes that are set to launch at system bootup or login as well as when you launch other built-in Windows programmes like Internet Explorer, Explorer, and media players. Ones in your starting folder, Run, RunOnce, and other Registry entries are examples of these applications and drivers. Auto-start services, toolbars, browser assistance objects, Winlogon alerts, and many other things are reported by Autoruns. Other autostart tools can't compare to Autoruns in any manner. (Markruss, Autoruns for windows - sysinternals)

Steps Taken to Generate the Keylogger Executable

1. Git Clone

```
C:\Users\IEUser>git clone https://github.com/PushpenderIndia/technowlogger.git
Cloning into 'technowlogger'...
remote: Enumerating objects: 616, done.
remote: Counting objects: 100% (138/138), done.
remote: Compressing objects: 100% (90/90), done.
remote: Total 616 (delta 69), reused 84 (delta 43), pack-reused 478
Receiving objects: 100% (616/616), 15.90 MiB | 1.09 MiB/s, done.
Resolving deltas: 100% (319/319), done.
```

2. Installing all the Requirements through Python

```
cmd Command Prompt
C:\Users\IEUser>python --version
Python 3.11.1

C:\Users\IEUser>cd technowlogger

C:\Users\IEUser\technowlogger>python -m pip install -r requirements.txt

3. Initializing Keylogger

```
PS C:\Users\IEUser\technowlogger> python technowgen.py -h

Author: Pushpendler | GitHub: @PushpendlerIndia

usage: technowgen.py [-h] [-i INTERVAL] [-t TIME_PERSISTENT] [-w] [-l] [-s] [-b BIND] [-d]
                     [-x SMTP_SERVER] [-y SMTP_PORT] [--icon ICON] [-e EMAIL] [-p PASSWORD] [-o
                     OUT]

TechNowLogger v2.2

Optional Arguments:
-h, --help            show this help message and exit
-i INTERVAL, --interval INTERVAL
                     Time between reports in seconds. default=120
-t TIME_PERSISTENT, --persistence TIME_PERSISTENT
                     Becoming Persistence After __ seconds. default=10
-w, --windows         Generate a Windows executable.
-l, --linux           Generate a Linux executable.
-s, --steal-password Steal Saved Password From Victim Machine [Supported OS :
                     Windows]
-b BIND, --bind BIND AutoBinder : Specify Path of Legitimate file.
-d, --debug           Payload Will Run In Foreground with CMD Window, To get Appropriate
                     Execution Error
-x SMTP_SERVER, --smtp SMTP_SERVER
                     Enter custom email smtp server. default=smtp.google.com
-y SMTP_PORT, --port SMTP_PORT
                     Enter custom email smtp port. default=587

Required Arguments:
--icon ICON           Specify Icon Path, Icon of Evil File [Note : Must Be .ico].
-e EMAIL, --email EMAIL
                     Email address to send reports to.
-p PASSWORD, --password PASSWORD
                     Password for the email address given in the -e argument.
-o OUT, --out OUT     Output file name.
```

Report From:

Operating System: Windows 10 10.0.17763
Computer Name: MSEDGEWIN10
User: IEUser

Keylogger sending screenshot of Victims computer at regular intervals which might potentially contain private information such as the Victims Account Passwords, Bank Details etc.

Static Analysis

1. Through PEview we can see the time and date when the keylogger was packed.

The screenshot shows the PEview interface with the file 'output_file.exe' open. The left pane displays the file structure tree, and the right pane shows a table of file header fields with their corresponding values. The 'IMAGE_FILE_HEADER' field is highlighted in blue.

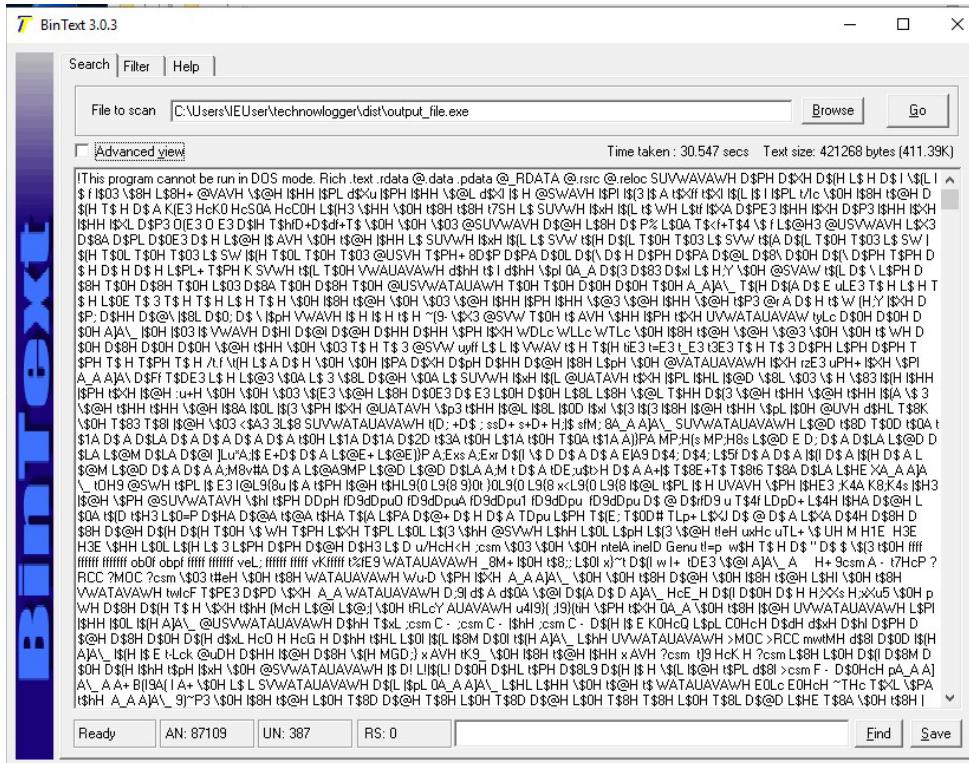

pFile	Data	Description	Value
00000104	8664	Machine	IMAGE_FILE_MACHINE_AMD64
00000106	0007	Number of Sections	
00000108	63960A00	Time Date Stamp	2022/12/11 Sun 16:49:04 UTC
0000010C	00000000	Pointer to Symbol Table	
00000110	00000000	Number of Symbols	
00000114	00F0	Size of Optional Header	
00000116	0022	Characteristics	
	0002		IMAGE_FILE_EXECUTABLE_IMAGE
	0020		IMAGE_FILE_LARGE_ADDRESS_AWARE

2. PEiD was able to identify 6 types of signature of the Keylogger

The screenshot shows the PEiD interface. At the top, there are input fields for 'Entrypoint' (00007F3A), 'File Offset' (0000733A), 'Linker Info' (14.0), and 'EP Section' (.text). Below these are buttons for 'First Bytes' (E8,DE,03,00) and 'Subsystem' (Win32 GUI). A message box states 'Nothing found [Overlay] *'. At the bottom are buttons for 'Multi Scan', 'Task Viewer', 'Options', 'About', 'Exit', and checkboxes for 'Stay on top' and '->'. The bottom half of the window is titled 'Section Viewer' and contains a table of sections with their names, virtual offsets, sizes, and flags.

Name	V. Offset	V. Size	R. Offset	R. Size	Flags
.text	00001000	00059A94	00000400	00059C00	60000020
.rdata	0005B000	00010B52	0005A000	00010C00	40000040
.data	0006C000	00003CA0	0006AC00	00000C00	C0000040
.glibs	00070000	00000174	0006B800	00000200	40000040
.rsrc	00071000	00001258	0006BA00	00001400	40000040
.reloc	00073000	00002E2C	0006CE00	00003000	42000040

3. The BinText returns jumbled letters, numbers and symbols which indicate that the file is packed.

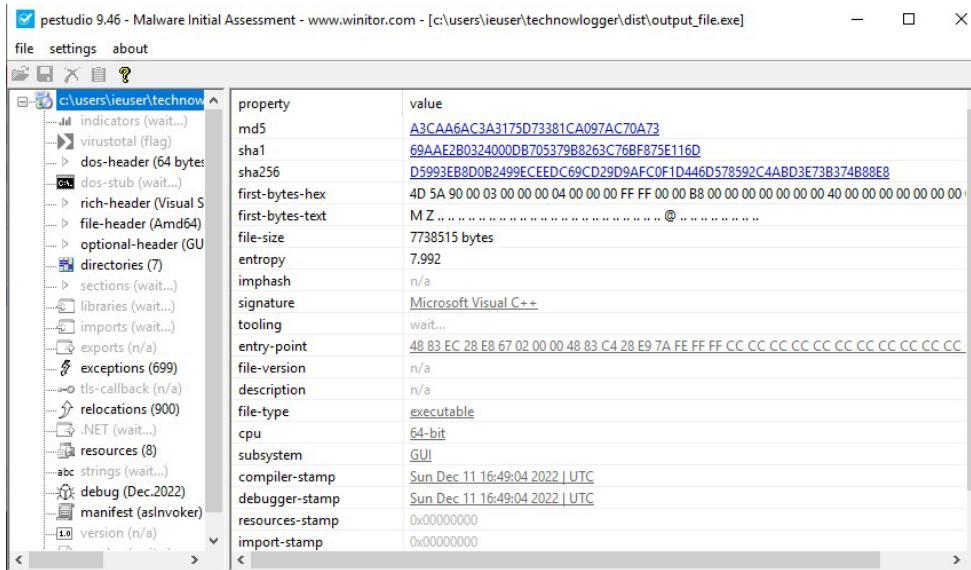

4. Dependency Walker shows us the Five type of DLLs which is used by the Keylogger. Namely USER32.DLL, COMCTL32.DLL, KERNEL32.DLL, ADVAPI32.DLL and GDI32.DLL

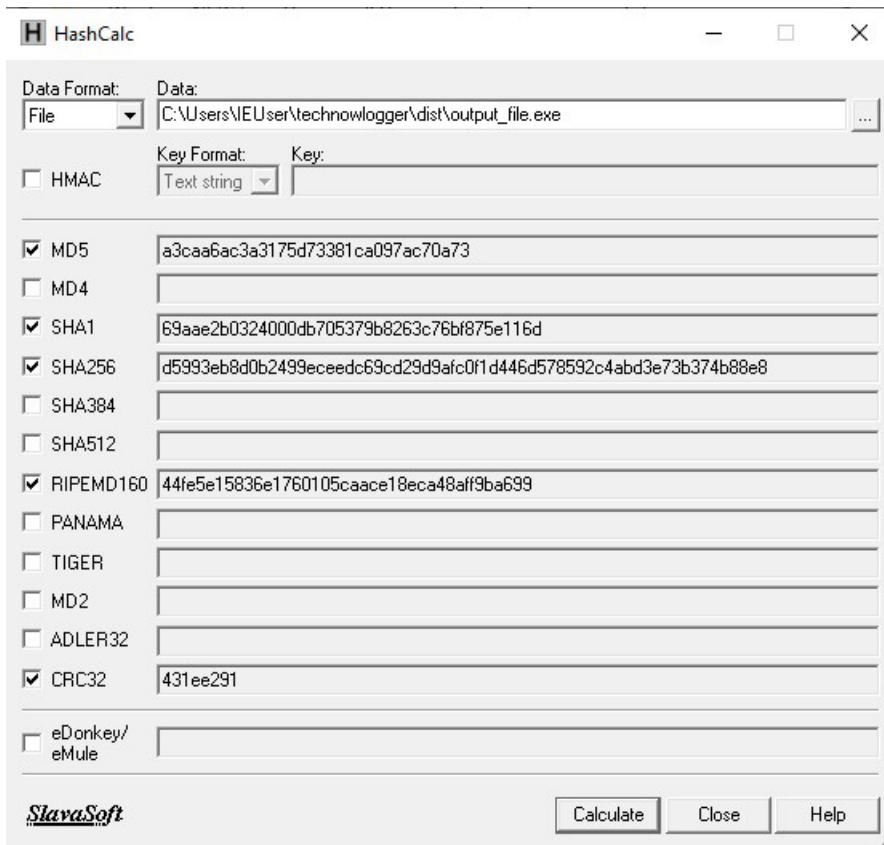

Dependency Walker - [output_file.exe]						-	
	File	Edit	View	Options	Profile	Window	Help

For Help press F1

5. PEStudio returns some specifications of the Keylogger such as MD5, sha1 and Sha256 among other general specifications, nothing precise we can use.

6. HashCalc returns the Keylogger's MD5, SHA1, SHA256, RIPEMD160 and CRC32 which can be used to further analyze the Keylogger through VirusTotal, Hybrid Analysis etc.

7. Hybrid Analysis returns us the following output:

This report is generated from a file or URL submitted to this webservice on December 11th 2022 11:57:15 (UTC)
Guest System: Windows 10 64 bit, Professional, 10.0 (build 16299).
Report generated by Falcon Sandbox v9.5.1 © Hybrid Analysis

malicious
Threat Score: 100/100
AV Detection: 47%
Labeled as: Win/malicious_confidence_90%

Incident Response Report False-Positive

Risk Assessment

Spyware	Hooks API calls Sets a global windows hook to intercept keystrokes
Persistence	Creates a fake system process Installs hooks/patches the running process Modifies auto-execute functionality by setting/creating a value in the registry Spawns a lot of processes Writes data to a remote process
Fingerprint	Queries process information Tries to gather information about running processes on a system
Evasive	Input file contains API references not part of its Import Address Table (IAT) Marks file for deletion Stops a system service using net.exe
Network Behavior	Contacts 4 hosts. View all details

Network Related

Sends network traffic on a typical mail related ports

details "Mail traffic to 52.96.239.182 on port 587 (SMTP), "Mail traffic to 52.96.226.150 on port 587 (SMTP)
"Mail traffic to 52.96.170.70 on port 587 (SMTP), "Mail traffic to 52.96.190.230 on port 587 (SMTP)
source Network Traffic
relevance 6/10
ATT&CK ID T1571 (Show technique in the MITRE ATT&CK™ matrix)

Spyware/Information Retrieval

Sets a global windows hook to intercept keystrokes

details "output_file.exe" set a windows hook with filter "WH_KEYBOARD_LL"
"svchost.exe" set a windows hook with filter "WH_KEYBOARD_LL"
source API Call
relevance 10/10
ATT&CK ID T1056.004 (Show technique in the MITRE ATT&CK™ matrix)

Unusual Characteristics

Spawns a lot of processes

details Spawned process "output_file.exe" (Show Process)
Spawned process "output_file.exe" (Show Process)
Spawned process "cmd.exe" with commandline "/c ver" (Show Process)
Spawned process "cmd.exe" with commandline "/c net stop "Security Center"" (Show Process)

Hybrid Analysis shows us that the Keylogger is a network based Malware and that it's a type of Spyware.

Dynamic Analysis

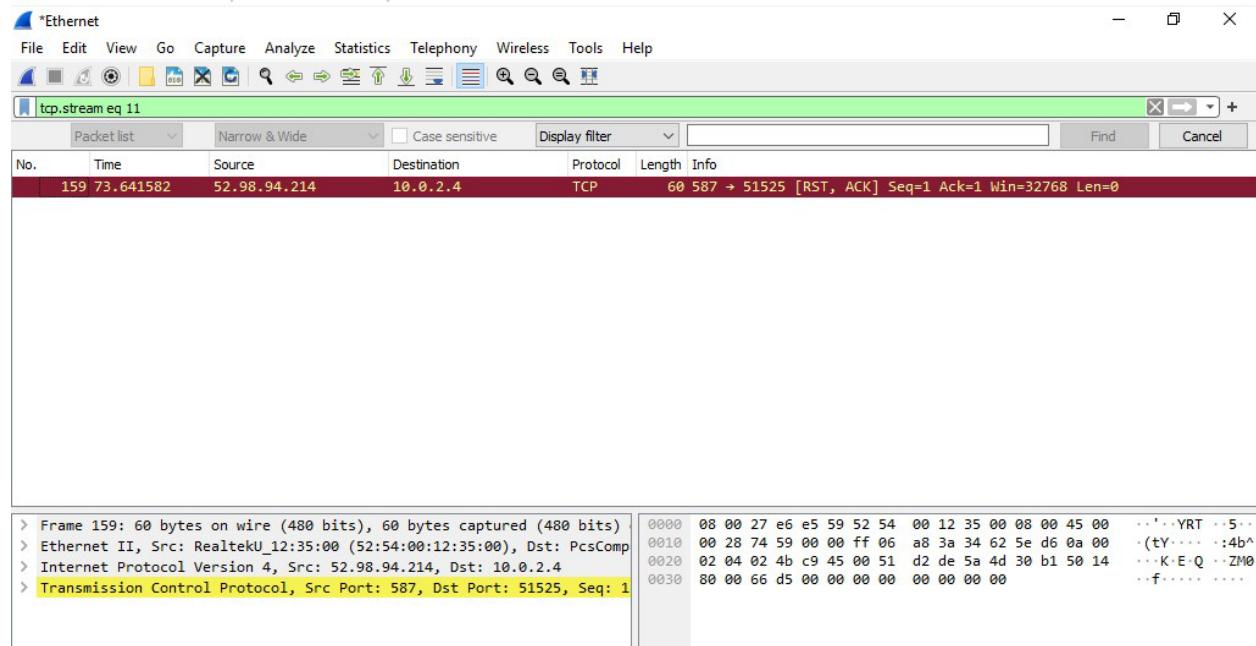

1. The Process Monitor Lists out all the DLLs utilized by the Keylogger while its being executed in the background. One of the DLLs called by the Keylogger is rpcrt4.dll which is a network based dll. This indicates that the Keylogger has some networking functionality.

3. Wireshark shows us that the Keylogger is communicating with Port 587, which is the default SMTP(Simple Mail Transfer Protocol). This indicates the Keylogger is communicating with a third party through mails using port 587.

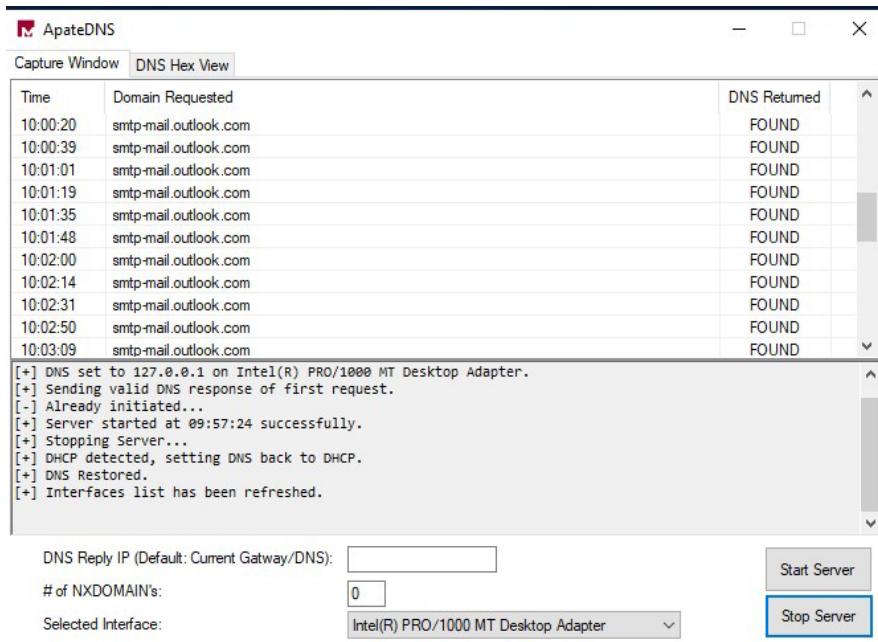

4. Fiddler does not show any activity of the Keylogger which means that the Keylogger is very well hidden and cannot be discovered by all the applications.

5. RegShot compared the Number of Registries used by the Computer before and after execution of Keylogger. As we can see from the screenshot below, 25 Additional Registries were used by the Keylogger.

6. ApateDNS shows us that there is a clear communication between the Computer and Outlook. From the analysis we have gathered until now, we can conclude that the Keylogger is communicating with a third party through sending mail to the third party's outlook account.

7. AutoRun was not able to detect the Keylogger which implies how hard it is to detect Keyloggers.

The screenshot shows the Autoruns application interface. The title bar reads "Autoruns - Sysinternals: www.sysinternals.com". The menu bar includes File, Search, Entry, Options, Category, and Help. Below the menu is a toolbar with icons for Winsock Providers, Print Monitors, LSA Providers, Network Providers, WMI, Office, Codecs, Boot Execute, Image Hijacks, Applnit, Known DLLs, WinLogon, Everything, Logon, Explorer, Internet Explorer, Scheduled Tasks, Services, and Drivers. A "Quick Filter" search bar is present. The main window displays a table of startup entries under the "Logon" category. The columns are "Autoruns Entry", "Description", and "Publisher". The entries listed are:

Autoruns Entry	Description	Publisher
HKCU\Software\Microsoft\Windows\CurrentVersion\Run		
OneDrive	Microsoft OneDrive	(Verified) Microsoft
svchost		(Not Verified)
HKLM\System\CurrentControlSet\Control\Terminal Server\Wds\rdpwd\StartupPrograms		
rdclip	RDP Clipboard Monitor	(Verified) Microsoft
HKLM\Software\Microsoft\Windows\CurrentVersion\Run		
bginfo	BGInfo - Wallpaper text configurator	(Verified) Microsoft
SecurityHealth	Windows Security notification icon	(Verified) Microsoft

At the bottom left, there is a "Ready" message.

4. Conclusion

In this research project, we discovered that the keylogger is a highly effective tool used to spy on the target computer and record all keyboard inputs as well as screenshot the target computers activities without informing the target computers user, which may contain the victim's personal information like a password or bank account information. We discovered that the Keylogger is a network-based spyware that logs the victim's activities and sends them over Port 587, the standard SMTP(Simple Mail Transfer Protocol), to a third party's mail account.

Recommendations on how to guard against potential keyloggers:

1. Install Anti-Virus software on each device you own. Typically, malicious keyloggers infiltrate machines using software based techniques. An active barrier to protect against viruses will be present if you use an Anti-Virus Software.
2. Maintain software updates for all other devices. The most recent security updates for your operating system, applications, and web browsers should all be installed. Be careful to download and install updates as soon as they are available.
3. By using 2-Step verification, keylogging attacks may be avoided. To confirm identification, a pin code must be entered into a cell phone by text message. Even if a hacker manages to get your login and password using a keylogger, it prohibits them from accessing your account.
4. If you don't download cracked software, you will be saved from potential Keyloggers. Malware is frequently present in cracked software. Although they are free, they could be harmful to your PC. Unintentionally installing a keylogger that poses as computer software is possible.
5. To stop keyloggers from recording the precise keys you press on the keyboard, key encryption software encrypts those keys as you press them. As soon as users go to the programme, they hide the keystrokes. Therefore, a keylogger will only be able to record the characters that were used to encrypt the sensitive data.
6. Unknown external hard discs and USB devices should never be used. In order to persuade you to grab and use them, many crooks leave these devices in public areas. Once connected, they can penetrate and plant a keylogger in your computer as well.
7. Keep an eye on your computer and mobile devices. Your smartphone could be all that a thief needs if they can take it or even just get their hands on it briefly, they can plant a keylogger in it. Keep your gadgets close by to help stop keyloggers from being planted.

8. Install a password manager since keyloggers can't record your inputs if you don't enter them in. You can protect your passwords and personal information by using programmes that automatically fill out forms.
9. Changing your passwords often is another strategy to reduce the potential impact from keylogging. This is not only a suggested data security practise, but it could also make the data that a keylogger has taken unusable.
